CSE344 – Final Projesi Raporu

Abdulhakim Emre ARTIŞ - 141044034

Server.c:

struct clientInfo -> İsim, öncelik, ödev, ödevin yapılış süresi bilgilerini tutar.

struct providerInfo->İsim,sıradaki client bilgileri, client sayısı, providerın aktif olup olmadığı, performans, ücret, online olma süresi, ücret, toplam online olma süresi, yapılan ödev sayısı bilgilerini tutar.

- -Provider bilgilerini belirtilen dosyadan okuyarak kişi sayısı kadar yer alır ve bilgilerini doldurur.
- -Her provider için thread oluşturulur.
- -Bağlantı için socket ve her bağantı için ayrı thread oluşturulur.
- -Her bağlantı sağlandığında önceliğine göre en iyi eşleşme yapılan provider'ın(mutex lock yapılarak) ödev sırasına eklenir, provider dan gelen cevap client'a iletilir.
- -terminalden SIGINT sinyali gelene kadar devam eder, sinyalin gelmesiyle provider bilgileri print edilir ve ayrılan yerler free edilir.

PROVIDER:

Ödev sırası boşsa gelene kadar bekler . Geldiğinde işlemi yapıp ödev sırasını düzenler . Ardından ödev sonucu bağlantı sağlayan thread aracılığıyla client a gönderilir.

Client.c:

Parametlere göre ödev isteği socket aracılığıyla servera iletilir ve cevap gelene kadar beklenir. Giden ve gelen bilgiler terminale print edilir .

<u>CSE344 – System Programming – Final Projesi PDF Özeti</u>

SERVER

✓	Admits as command line argument: - the connection port for listening to clients - file of providers - and the log file
✓	Server reads providers: Provider -> "name , price , quality ,time"
✓	Server creates a pool of provider threads. THREADLERİN SONLANMASI???
✓	Every new connection MUST be handled as a new thread.
✓	This new thread will post the job to provider(if available) and wait for it to finish.
✓	All server/provider messages must be logged at a log file and printed on stderr.
~	The task queue of every provider has size 2. If provider's queue is full, then the server must forward the task to the next best performing provider.
✓	Once a client connects, your server will forward the homework to the corresponding provider.
~	If no provider is available an error message "NO PROVIDER IS AVAILABLE" will be sent to the client.
	Your server will continue to work until a termination signal is received, in which case it will first close up all client sockets by sending a polite message such as "SERVER SHUTDOWN" and terminate all provider threads.

CLIENT

- ✓ Every client commandline arguments:
 - client name as a string
 - priority 'C' for low cost || 'Q' for high quality || 'T' for high speed
 - the homework as an integer denoting degree
 - server address
 - server port address
- ✓ Will connect to the server send a request in the form of a simple string: "Hileci C 45" the client's name is Hileci, his priority is low cost and homework is cos(45)

Sample output for a client console:

- ✓ -Client Hileci is requesting Q 45 from server 127.0.0.1:5555
- ✓ -Hileci's task completed by Ayse in 7.53 seconds, cos(45)=0.707, cost is 900TL, total time spent 7.89 seconds.

$\overset{ o}{}$ PROVIDER

- ✓ Every provider will wait for tasks in her/his queue, complete the task, sleep for a random duration between 5-15 seconds (to simulate hard work...), and return its result to the client.
- ✓ Once the login time is up, the provider will logout and her/his thread will be terminated.

Rules

- Your program must handle eventual errors gracefully according to the POSIX traditions.
- Your program must print usage information in case of incorrect or missing command line arguments.
- "You are expected to submit a report explaining in detail how your project design provides the required behavior and how you have solved any eventual problems you have encountered." Report format will be pdf.
- Provide a makefile to compile your homework. Do not run your program inside makefile. Just compile
